

SKYDIVE·LIVE

GENERATION V5 · DUAL ANTENNA

Never lose the picture.

The jumper turns. One antenna loses it.

Two don't

THE PROBLEM

A body is a **shadow**.

In belly flight (face down) the antenna points down — a clear line to the ground. The moment the jumper goes **head-down (head first)**, their own body slides between the transmitter and the ground. A single antenna **drops out** — exactly at the most spectacular moment.

Flip him head-down. Switch in the second antenna.

Belly

Sit

Head-down

Back

1 antenna
patch only

2 antennas
patch + dipole

THE SOLUTION

One looks down. One looks up.

The **patch** radiates toward the ground — perfect in belly flight. The **dipole** sits on top — it catches the picture when the jumper goes head-down. An **RF switch** picks the better antenna in real time, whichever has the clearer view.

MODULAR

Flush. One block.

The second antenna sits **flush with the shell** — in the top lid and the -X end cap, **screwed in, not plugged on**. No bump, no snag risk. Print the transmitter **with or without** the antenna — same clean form.

AND ON THE GROUND

Switched up top. Caught many ways below.

WHERE WE STAND — HONESTLY

The CAD is done. The print is next.

MACHINE-VERIFIED

- ✓ **Transmitter print-ready** — 6 parts watertight, gate green (via trimesh, not just claimed)
- ✓ **Every part has its place** — fit, mounting, cable routing checked (boolean, 0 collisions)
- ✓ **Antenna flush** — top lid + -X end cap screwed in, coax feedthrough, gate green
- ✓ **Dual antenna worked out** — switched, one U.FL, ground diversity

Turn however you want. We hold the link.

Two antennas. A picture that never drops out.
Next, the printed proof speaks.
